ABSTRACT

Objective—Leptin is an adipocyte hormone that plays a major role in energy balance. Leptin receptors in the hypothalamus are known to signal via distinct mechanisms including signal transducer and activator of transcription-3 (STAT3) and phosphoinositol-3 kinase (PI3K). Here, we tested the hypothesis that extracellular signal regulated kinase (ERK) is mediating leptin action in the hypothalamus.

Research Design and Methods—Biochemical, pharmacological and physiological approaches were combined to characterize leptin activation of ERK in the hypothalamus in rats.

Results—Leptin activates ERK1/2 in a receptor-mediated manner that involves JAK2. Leptin-induced ERK1/2 activation was restricted to the hypothalamic arcuate nucleus. Pharmacological blockade of hypothalamic ERK1/2 reverses the anorectic and weight-reducing effects of leptin. The pharmacologic antagonists of ERK1/2 did not attenuate leptin induced activation of STAT3 or PI3K. Blockade of ERK1/2 abolishes leptin-induced increases in sympathetic nerve traffic to thermogenic brown adipose tissue, but does not alter the stimulatory effects of leptin on sympathetic nerve activity to the kidney, hindlimb or adrenal gland. In contrast, blockade of PI3 kinase prevents leptin-induced sympathetic activation to the kidney, but not to brown adipose tissue, hindlimb or adrenal gland.

Conclusions—Our findings indicate that hypothalamic ERK plays a key role in the control of food intake, body weight, and thermogenic sympathetic outflow by leptin, but does not participate in the cardiovascular and renal sympathetic actions of leptin.
Leptin is a largely adipocyte-derived hormone that can act in the central nervous system to decrease appetite and increase energy expenditure thereby leading to decreased body weight (1). Central actions of leptin play an important role in the regulation of several other physiological functions including reproductive function (2), bone formation (3) and regional sympathetic nerve activity (SNA) subserving thermogenic metabolism and cardiovascular function (4).

Leptin exerts its effects via interaction with specific receptors located in distinct classes of neurons. While several isoforms of the leptin receptor have been identified, the Ob-Rb form that include the long intracellular domain that has signaling capacity appears to mediate most of the biological effects of leptin (5;6). The signal transducer and activator of transcription-3 (STAT3) pathway was the first signaling mechanism associated with the leptin receptor (7). Neural-specific inactivation of STAT3 leads to hyperphagia and obesity in mice (8). In addition, disrupting the ability of the leptin receptor to activate STAT3 pathway in mice leads to severe obesity and several other neuroendocrine abnormalities (9-11). More recently, other intracellular signaling mechanisms including phosphoinositol-3 kinase (PI3K) (12), AMP-activated protein kinase (13) and mammalian target of rapamycin (14) have been shown to play an important role in the action of leptin on food intake.

Extracellular signal regulated kinase (ERK), a member of the mitogen activated protein kinase (MAPK) family, is an additional downstream pathway of the leptin receptor (15). Leptin was shown to activate ERK1/2 in a time- and dose-dependent manner in cultured cells (16-18). Activation of ERK1/2 by leptin seems to be mediated through Src homology-containing tyrosine phosphatase 2 (Shp2) emanating from the tyrosine 985 (Tyr985) of the leptin receptor (19;20). Stimulation of ERK by leptin can also be achieved by direct interaction with Jak2 (15;19;20). In turn, in cell lines ERK appears to mediate the activation of c-fos (20) and ribosomal S6 kinase and S6 (21) by the leptin receptor.

This ERK pathway has been reported to mediate leptin effects in several tissues including cardiomyocytes (22;23), the immune system (24;25) and kidney (26). However, the physiological significance of this pathway for the hypothalamic-mediated effects of leptin remains poorly characterized. This study depicts the effect of leptin on hypothalamic ERK and investigates the potential role of this ERK pathway in mediating the effect of leptin on food intake, body weight and regional sympathetic outflow.

**RESEARCH DESIGN AND METHODS**

**Animals.** Male Sprague-Dawley, and lean and obese Zucker (fa) rats were obtained from Harlan Sprague-Dawley. Rats were housed at 23 °C with a 12-h light/dark cycle (light on at 6AM) and allowed free access to standard rat chow and water. Rats receiving injections in the third cerebral ventricle were equipped with intracerebroventricular (ICV) cannulas at least one week before the experimentation as described previously (27). Ethical approval of all the studies was granted by the University of Iowa Animal Research Committee.

**Biochemical studies.** Rats were fasted overnight before ICV administration of murine leptin (R&D Systems). Rats were killed at the indicated time points by CO₂ asphyxiation.
Role of ERK in leptin effects

Hypothalamus was quickly removed from each rat and the total proteins extracted and stored at -80°C. Protein samples of homogenized tissues or immunoprecipitates (to assess the effect of leptin on PI3K, immunoprecipitates were obtained by incubating protein samples with anti–IRS-1 antibody (E-12, Santa Cruz) in presence of protein A–sepharose) were resolved with 10% SDS-PAGE and PVDF membranes were incubated with specific antibodies for STAT3 (C-20, Santa Cruz Biotechnology), phospho-STAT3 (Tyr705, Cell Signaling), ERK1/2 (Cell Signaling), phospho-ERK1/2 (Thr202/Tyr204, Cell Signaling), p38 MAPK (H-147, Santa Cruz Biotechnology), phospho-p38 MAPK (Thr180/Tyr182, Cell Signaling) or PI3K p85 (Cell Signaling). Blots were detected with ECL and their intensity measured for quantitative analysis. To examine the effect of JAK2 blockade on the increase in ERK1/2 phosphorylation induced by leptin different doses of AG490 were administered ICV 1 h before leptin (10 μg). To assess the effect of leptin on p38 MAPK in the skeletal muscle rats were injected intraperitoneally with leptin (1 μg/g body weight) and sacrificed 10 min after the treatment. Skeletal muscle from the hindlimb was removed and the extracted proteins assayed for phospho-p38 MAPK as described above.

Immunohistochemistry. Rats were fasted overnight and treated with vehicle or leptin either ICV (10 μg) or intraperitoneally (1 μg/g body weight). Five to 20 min after the treatment rats were euthanized by CO₂ asphyxiation and then perfused transcardially with PBS followed by 4% paraformaldehyde in PBS. The brains were removed, postfixed in 4% paraformaldehyde at 4°C overnight. Fixed brains were washed 3 times with PBS and incubated in 30% sucrose in PBS. Coronal sections (30 μm) were cut with a freezing Microm cryostat. Free-floating sections were washed with PBS and permeabilized with 0.1% Triton X-100 in PBS. Sections were then incubated overnight at 4 °C with a mouse phospho-ERK antibody (1:100, sc-7383 from Santa Cruz Biotechnology) in 0.2% goat serum followed by 1 h incubation at room temperature with a secondary antibody, rhodamine (TRITC)-conjugated donkey anti-mouse IgG (1:100, code number 715-025-150 from Jackson ImmunoResearch Laboratories Inc.).

For double labeling, brains sections were processed for the localization of phospho-ERK as above. Rabbit antibodies recognizing proopiomelanocortin (POMC, 1:50, H-029-30 from Phoenix Pharmaceuticals Inc) or neuropeptide Y (NPY, 1:50, AB1915 from Chemicon International) were used to identify the neurons in which leptin activate ERK. Biotin-SP-conjugated donkey anti-rabbit IgG (1:100, code number 711-065-152 from Jackson ImmunoResearch Laboratories Inc.) was used as secondary antibody. Primary antibodies were tested separately before performing the double immunostaining. Additional control experiments consisted in the omission of primary or secondary antibodies in each case.

Further processing for immunodetection was performed using kits (Vector Laboratories) following manufacturer’s instruction. Slices were mounted on slides, coverslipped and visualized using a Nikon eclipse E600 fluorescence microscope equipped with a SPOT RT digital camera.

Food intake and body weight studies. Food was removed from the individually caged rats the day before the study. Rats were given a single ICV injection of PD98059 (5 μg), U0126 (7 μg), vehicle
Role of ERK in leptin effects

(DMSO; 2 μl) or artificial cerebrospinal fluid (aCSF; 2 μl) followed 15 min later by an intraperitoneal administration of leptin (1 μg/g body weight) or vehicle (saline) or ICV injection of 5 μg of MTII or corticotrophin releasing factor. The doses of the various drugs were based on our previous studies (27;28). Food was returned 1 h after the last injection corresponding to the onset of the dark cycle. Food intake and body weight were then recorded after 4 h and 24 h.

**Study of the sympathetic nervous system.** Anesthetized rats were instrumented for direct multifiber recording of regional SNA as described (27;28). BAT SNA was recorded simultaneously with SNA to kidney, hindlimb or adrenal gland. After baseline recordings of SNA were obtained, each animal received 2 ICV injections. Rats received first PD98059 (5 μg), U0126 (7 μg), LY294002 (5 μg) or vehicle (DMSO; 2 μl) followed 15 min later by leptin (10 μg) or saline. After ICV administration of experimental agents SNA measurements were made every 15 min for 6 hours. The data for SNA are expressed as percentage change from baseline.

**Statistical analysis.** All results are expressed as mean ± SEM and analyzed using Student’s t-test, one- or two-way analysis of variance (ANOVA). When ANOVA reached significance, a post-hoc comparison was made using Bonferroni or Newman-Keuls tests. A value of P < 0.05 was considered to be statistically significant.

**RESULTS**

To investigate the hypothesis that the ERK pathway is important for leptin action in the central nervous system, we first assessed whether leptin activates this enzyme in the hypothalamus, in vivo. The effect of ICV administration of leptin on the activity of STAT3 and ERK1/2 in the hypothalamus was examined in Sprague-Dawley rats. As previously reported (7;12;13), leptin caused a robust activation of the STAT3 in mediobasal hypothalamic extracts (Fig. 1A). Leptin also caused a rapid activation of hypothalamic ERK1/2 with a maximum effect at 5-15 min (Fig. 1B), consistent with previous findings (29;30). This response was dose-dependent (5 and 10 μg of leptin increased ERK1/2 activity by 3.4- and 4.3-fold, respectively). In peripheral tissues, such as the skeletal muscle, leptin has been shown to activate different isoforms of MAPK (31). Therefore, we examined whether leptin alters the activity of another hypothalamic isoform of MAPK. Leptin did not affect the activity of p38 MAPK in the hypothalamus (Fig. 1C). Intraperitoneal (IP) administration of leptin (1 μg/g body weight) did, however, cause a 3.1-fold increase (P < 0.01) in p38 MAPK in skeletal muscle (data not shown).

Leptin activation of ERK1/2 appears to be mediated by the leptin receptor since it activates hypothalamic ERK1/2 in the Zucker lean rat, but not in the leptin receptor deficient obese Zucker rat (Fig. 2A). Blockade of JAK2 with AG490 inhibited, in a dose-dependent manner, the activation of ERK1/2 by leptin (Fig. 2B), demonstrating that the leptin receptor modulates the activity of ERK1/2 via JAK2. These data demonstrate that in the hypothalamus the effect of leptin on ERK is receptor mediated, involves JAK2, and is specific to ERK1/2 isoforms.

Within the hypothalamus, the leptin receptor has been detected in several nuclei including the arcuate, ventromedial, paraventricular and dorsomedial nuclei (32;33). We used an immunohistochemical approach to identify the hypothalamic nuclei in which...
ERK1/2 is activated by leptin. Both systemic and central administration of leptin caused a marked increase in the immunoreactive ERK1/2 in the arcuate nucleus (Fig. 3A). In contrast, no increase in ERK activity was observed in hypothalamic nuclei other than the arcuate nucleus (in Fig. 3B the paraventricular nucleus is shown as an example) or in extra-hypothalamic including the nucleus tractus solitarii in the brainstem (data not shown). These data suggest that leptin activation of hypothalamic ERK1/2 is selectively localized in the arcuate nucleus.

Two classes of neurons account for leptin sensitivity within the arcuate nucleus (32-34): first, a catabolic pathway represented mainly by proopiomelanocortin (POMC) neurons that is activated by leptin; and second, an anabolic pathway represented principally by the neuropeptide Y (NPY) neurons that is inhibited by leptin. We, therefore, used double staining to determine whether activation of ERK1/2 by leptin occurs in one specific neuronal population. Interestingly, all the neurons in which the ERK1/2 immunoreactivity was increased by leptin were POMC positive (Supplemental Fig. 1A). No activation of ERK1/2 was observed in NPY neurons (Supplemental Fig. 1B). These data seems to suggest that ERK mediates leptin action through an effect on POMC neurons.

To test the hypothesis that ERK is crucial for the physiological action of leptin, we assessed the effect of ERK inhibition (PD98059 and U0126) (35-37) on the feeding and body weight responses to leptin. We first verified that baseline food intake and body weight were not altered by the administration of the vehicle (DMSO) or the ERK inhibitors in the third cerebral ventricle (Fig. 4A-C). Treatment with leptin at the onset of the dark phase significantly reduced food intake at both 4 h (Fig. 4A) and 24 h (Fig. 4B). This effect was accompanied by decreased body weight at 24 h after treatment with leptin (Fig. 4C). Pretreatment with the ERK inhibitors (PD98059 or U0126) reversed the decrease in food intake induced by leptin at 4 h (Fig. 4A) and 24 h (Fig. 4B). The ability of leptin to decrease body weight was also blocked by the PD98059 and U0126 (Fig. 4C). To exclude the possibility that blockade of the anorectic and weight-reducing actions of leptin by PD98059 and U0126 may be due to inhibition of other mediators of leptin action such as STAT3 and PI3K (which are known to play an important role in leptin effects on food intake) (9;12) we tested the effect of leptin on the activity of ERK1/2, STAT3 and PI3K in presence of PD98059 and U0126. As expected, leptin activation of hypothalamic ERK1/2 was prevented in the presence of PD98059 or U0126 (Fig. 5). In contrast, stimulation of hypothalamic PI3K and STAT3 by leptin was not affected by the presence of these inhibitors (Fig. 5). These data demonstrate that blockade of the effect of leptin on food intake and body weight by PD98059 and U0126 is due to inhibition of ERK1/2 and not to blockade of leptin-induced STAT3 or PI3K activation.

Because ERK is a key enzyme for many intracellular signaling processes, we addressed the specificity of blockade of leptin-induced anorexia and weight loss by testing the feeding- and weight-reducing actions of other stimuli, i.e. an agonist of the melanocortin receptors, Melatonan II (MTII) and corticotrophin releasing hormone. ICV MTII caused a significant decrease in food intake and body weight at 4 h and 24 h (Fig. 4D-F and data not shown). ICV pre-treatment
with PD98059 or U0126 did not alter the effect of ICV MTII on food intake and body weight (Fig. 4D-F). In addition, the anorectic and weight-reducing actions of ICV administration of corticotrophin-releasing hormone were not affected by the ERK inhibitors (data not shown). Together, these findings show that the pharmacologic inhibitors of ERK produce a selective blockade of the effects of leptin and do not attenuate the responses to other agonists such as MTII and corticotrophin releasing hormone.

Leptin stimulation of the sympathetic nervous system regulates diverse physiological processes including energy expenditure and cardiovascular function. The possible role of hypothalamic ERK in the control of the sympathetic nerve traffic by leptin was investigated. ICV leptin caused regional sympathetic activation including increases in sympathetic nerve outflow to BAT (Fig. 6A), kidney (Fig. 6C), hindlimb (Fig. 6E) and adrenal gland (Fig. 6G). Selective inhibition of ERK prevented leptin-induced sympathetic activation to thermogenic BAT (Fig. 6B). This effect of ERK inhibition on BAT sympathetic activation to leptin was dose-dependent (BAT sympathetic activation to leptin was 183 ± 13%, 114 ± 19% and 14 ± 11% in the presence of vehicle, 3 μg and 7 μg of U0126, respectively, P < 0.001). In contrast, PD98059 or U0126 did not alter renal (Fig. 6D), lumbar (Fig. 6F) and adrenal (Fig. 6G) sympathetic nerve responses to leptin. In order to examine whether the control of sympathetic outflow to thermogenic BAT by leptin exclusively involves ERK, we assessed the effect of inhibition of another pathway that has been shown to play a major role in the feeding and sympathetic responses to leptin, PI3K (12;38). Inhibition of PI3K with LY294002 significantly attenuated renal sympathetic activation to leptin (Fig. 6D) which is consistent with our previous report (38). In contrast, PI3K inhibition with LY294002 failed to alter BAT (Fig. 6A), lumbar (Fig. 6F) or adrenal (Fig. 6G) sympathetic nerve responses to leptin. Taken together, these results demonstrate that leptin regulates different regional sympathetic nerve activities through distinct and contrasting intracellular signaling pathways with ERK contributing to the thermogenic BAT sympathetic response, but not renal, lumbar or adrenal sympathetic nerve responses to leptin.

DISCUSSION
We have characterized a new hypothalamic signaling mechanism of the leptin receptor. Our results show that leptin activates ERK1/2 in the arcuate nucleus, and that this pathway contributes to leptin control of food intake, body weight and thermogenic sympathetic outflow. Hypothalamic ERK appears to mediate selective leptin actions since its inhibition prevented some but not all actions of leptin. This suggests that modulation of the hypothalamic ERK pathway could affect leptin’s metabolic actions (appetite and thermogenic sympathetic metabolism) without altering its sympathetic cardiovascular and renal actions.

Previous studies have implicated hypothalamic ERK in the regulation of energy homeostasis. Indeed, fasting was shown to activate ERK in the hypothalamic arcuate and paraventricular nuclei in mice (39;40). Fasting-induced activation of hypothalamic ERK was reversed by re-feeding, suggesting that activation of ERK in the hypothalamus is relevant for energy balance (40). Our current findings that hypothalamic ERK contributes to the actions of leptin extend
the role of this ERK pathway in the control of energy homeostasis. Our results are in line with the observation that the development of obesity in mice with neuronal-specific ablation of Shp2 is related to the inability of leptin to stimulate ERK (41). To study the role of neuronal Shp2, Zhang et al. (41) used the cre-loxP system to create a conditional Shp2 mutant allele in mice. This allowed selective deletion of Shp2 in postmitotic forebrain neurons. Surprisingly, the predominant phenotype exhibited by this mouse model was the development of early-onset obesity. In subsequent studies, Zhang and associates found that leptin-induced phosphorylation of ERK1/2 in the arcuate nucleus of hypothalamus was dramatically reduced in mice with neuronal-specific ablation of Shp2 compared with the controls (41). In contrast, the ability of leptin to induce phosphorylation of arcuate STAT3 was preserved in this mouse model. Although the signaling cascade leading to the activation of ERK by the leptin receptor remains unclear (15), the inability of leptin to stimulate ERK in the absence of Shp2 suggests that this protein mediates leptin activation of ERK. However, recent findings challenge the importance of Shp2 in mediating leptin effects (42). This is based on the observation that in mice, mutation of the Tyr985 of the leptin receptor which blocks Shp2 recruitment did not recapitulate the obesity phenotype observed in mice in which Shp2 was deleted in the forebrain neurons (43) suggesting that, in vivo, Jak2-dependent mechanism may be the predominant pathway for the stimulation of ERK by the leptin receptor.

The downstream hypothalamic pathways controlled by the leptin receptor-ERK axis remain to be elucidated. Importantly, leptin activation of ERK seems to occur in the POMC neurons in the arcuate nucleus of the hypothalamus which narrows the search for the mechanisms that are controlled by the leptin receptor-ERK axis. However, additional studies are needed to analyze in more details the role of ERK in POMC vs. NPY neurons in mediating leptin action.

A key downstream target of the POMC neurons are neurons expressing melanocortin 4 receptors (MC4R) that are activated by α-melanocyte stimulating hormone (product of POMC) (33;34). Pharmacological blockade of MC4R reverse the effect of leptin on body weight and food intake (44) and deletion of the MC4R leads to severe obesity in mice (45). We have previously shown that blockade of the brain MC4R inhibits the renal, but not the brown adipose tissue, sympathetic nerve response to leptin (27). We also showed that leptin-induced renal sympathetic activation is absent in the homozygous MC4R knockout mice demonstrating the importance of this receptor in the control of renal sympathetic outflow by leptin (46). In addition, blockade of PI3K also inhibits renal but not brown adipose tissue SNA. In contrast to the role of MC4R and PI3K, blockade of ERK in this study inhibited SNA to brown adipose tissue but not the kidney. This supports the concept that differential intracellular mechanisms are involved in leptin-induced sympathetic activation to kidney and thermogenic brown adipose tissue. Sympathetic activity to brown adipose tissue is ERK-dependent while sympathetic activity to the kidney is PI3K- and MC4R-dependent.

These findings are in line with the notion that leptin controls various physiological processes through a variety of signaling mechanisms. For instance,
the STAT3 pathway appears to be involved in mediating the effects of leptin on food intake and energy homeostasis, but not on reproductive function, growth or glucose homeostasis (9). However, the relative role of each of the downstream pathways associated with the leptin receptor in the control of food intake by leptin remains perplexing because disrupting any of these pathways seems to have a profound effect on leptin-induced food intake. Disruption of the leptin receptor-STAT3 pathway causes hyperphagia in mice (9;10) which demonstrates that STAT3 is important for the control of food intake by leptin. In addition, the anorectic response to leptin can be reversed by blockade of PI3K (12;38) and ERK (present study).

Some limitations of the present study need to be addressed. First, our conclusions regarding the role of ERK in mediating leptin effects were based on acute studies. Whether chronic inhibition of these signaling pathways will result in similar effect as in the acute studies remain to be determined, but deletion of Shp2 is accompanied by increased food intake and obesity, presumably through disruption of ERK signaling. Second, the inhibitors we used in our studies to block ERK might have other non-specific actions. However, cell based assays and in vitro studies have shown that both PD98059 and U0126 appear to specifically suppress ERK signaling (35-37). These inhibitors have been widely used to suppress activation of ERK and examine the physiological roles of these enzymes. In addition, we have shown that pre-treatment with ERK inhibitors did not alter leptin-induced activation of STAT3 or PI3K and did not affect the appetite- and weight-reducing actions of MTII and corticotrophin releasing hormone. Third, our studies lack the neuroanatomical specificity regarding the brain nuclei where the ERK signaling pathway mediates the effects of leptin on food intake, body weight and BAT sympathetic outflow, because the inhibitors were administered ICV. Nonetheless, using an immunohistochemical approach we have shown that leptin activation of ERK occurs in the arcuate nucleus.

In conclusion, our experiments provide evidence that hypothalamic ERK is a significant downstream target for the effects of leptin to regulate food intake, body weight and thermogenic sympathetic outflow to brown adipose tissue. However, ERK appears not involved in leptin activation of sympathetic nervous system to other tissues such as the kidney, hindlimb and adrenal gland. These findings provide new insights into the intracellular mechanisms engaged by the leptin receptor to control various physiological functions.
