Obesity-Induced Endothelial Dysfunction Is Prevented by Deficiency of P-selectin Glycoprotein Ligand-1

Hui Wang,1 Wei Luo,1 Jintao Wang,1 Chiao Guo,1 Xiaohong Wang,1 Stephanie L. Wolffe,1 Peter F. Bodary,2 and Daniel T. Eitzman1

Endothelial dysfunction precedes atherosclerosis and represents an important link between obesity and cardiovascular events. Strategies designed to prevent endothelial dysfunction may therefore reduce the cardiovascular complications triggered by obesity. We tested the hypothesis that deficiency of P-selectin glycoprotein ligand-1 (Psgl-1) would improve the impaired endothelial dysfunction associated with obesity. Psgl-1 deficient (Psgl-1−/−) and wild-type (Psgl-1+/+) mice were fed standard chow or a high-fat, high-sucrose diet (diet-induced obesity [DIO]) for 10 weeks. DIO increased mesenteric perivascular adipose tissue (mPVAT) macrophage content and vascular oxidative stress in Psgl-1−/− mice but not in Psgl-1+/+ mice. Pressure myography using mesenteric arteries demonstrated that relaxation responses to acetylcholine were significantly impaired in DIO Psgl-1−/− mice, whereas DIO Psgl-1+/+ mice were protected from endothelial dysfunction with similar relaxation responses to Psgl-1+/+ or Psgl-1−/− mice fed standard chow. The superoxide scavenger 4-hydroxy-2,2,6,6-tetramethylpiperidinyloxy (TEMPOL) partially recovered impaired endothelial function induced by DIO. A neutralizing Psgl-1 antibody was also effective in preventing endothelial dysfunction and reducing mPVAT macrophage content induced by DIO. These results indicate that obesity in mice leads to endothelial dysfunction and reducing macrophage content and vascular oxidative stress in DIO increased mesenteric perivascular adipose tissue (mPVAT) surrounding mesenteric arteries demonstrated that relaxation responses to acetylcholine were signifi-

RESEARCH DESIGN AND METHODS

Animals. Male C57BL6/J and Psgl-1−/− mice were originally purchased from Jackson Laboratory (Bar Harbor, Maine). Psgl-1−/− were backcrossed to the C57BL6/J strain >16 generations before use in these experiments. Mice were fed a standard laboratory rodent diet (No. 5001, TestDiet, Richmond, IN) or a high-fat, high-sucrose diet (HFD; D12451, Research Diet Inc, New Bruns-

O

bosity is epidemic in the United States and is associated with increased risk for cardiovascular complications (1). Excess visceral adipose tissue may be the primary driver of the vascular risk associated with obesity because visceral fat is strongly associated with a chronic, low-grade inflammatory state characterized by increased macrophage activity in adipose tissue (2,3). The mechanism(s) by which obesity promotes vascular disease is unclear, but endothelial dysfunction has been demonstrated even in children with obesity (4,5). Endothelial dysfunction due to impairment of nitric oxide (NO) activity represents an early stage of many cardiovascular diseases (6).

P-selectin glycoprotein ligand-1 (Psgl-1) is the primary leukocyte ligand for P-selectin (P-sel) and an important ligand for E-selectin (E-sel) (7). Psgl-1 deficiency has been shown to reduce leukocyte-endothelial interactions in obesity and to reduce macrophage accumulation in gonadal fat pads (8). The purpose of this study was to determine the effect of Psgl-1 deficiency on endothelial dysfunction associated with obesity.

Original Article
excitation wavelength of 488 nm and emission wavelength of 597 to 610 nm. The intensity of fluorescence signal was quantified as arbitrary units using Image J software (National Institutes of Health, Bethesda, MD).

**Immunoblotting.** Mesenteric arteries were homogenized and lysed in E-PER lysis buffer (Thermo Scientific, Inc., Rockford, IL) supplemented with protease inhibitor cocktail (Roche, Branchburg, NJ). Protein concentration was assessed using BCA Protein Assay Kit (Thermo Scientific Inc.), and equal amounts of protein were resolved by SDS-PAGE and then transferred to polyvinylidene fluoride membranes by electroblotting. Nitrotyrosine expression was detected using a mouse anti-nitrotyrosine monoclonal antibody (Abcam, Cambridge, MA).

**Functional and mechanical studies of mesenteric and carotid arteries.** Mice were killed with intraperitoneal pentobarbital (80 mg/kg), and a segment of small intestine with attached mesentery was removed and placed into a silastic-elastic-lined petri dish filled with cold PBS equilibrated with 5% CO2 and 95% O2. The second-order branches of mesenteric artery were dissected, and surrounding fat and connective tissue were cleared. Vessel segments 2–3 mm in length were mounted onto glass cannulae of a pressure myograph (Living Systems Instrumentation, Burlington, VT). Cannulae were adjusted to the axial direction of the vessel until the vessel walls were parallel without any stretch. Vessels were equilibrated in PSS at 37°C for 60 min at 45 mmHg intraluminal pressure. The real-time dimension of the vessel wall was detected and analyzed by a video dimension analyzer (Living Systems).

Vascular reactivity was tested under no-flow conditions. After equilibration, vascular viability was tested using extraluminal applied norepinephrine (NE, Sigma, St. Louis, MO) 10^{-5} mol/L plus KC1 125 mMol/L. The vessels were considered viable when the constriction of the luminal area exceeded 60%. After washing, vascular contraction was assessed by measuring constriction in response to cumulatively applied NE (10^{-8} to 10^{-4} mol/L).

After washing and equilibration, endothelium-dependent relaxation was assessed by measuring the dilatory response to acetylcholine (Ach 10^{-5} to 10^{-4} mol/L; Sigma) in NE (10^{-5} mol/L) precontracted vessels. To determine the role of superoxide, Ach-induced vasorelaxation was examined after vessels were incubated for 30 min in 1 mMol/L 4-hydroxy-2,2,6,6-tetramethylpiperidinoloxyl (TEMPOL, Sigma), a superoxide scavenger. To evaluate NO bioavailability, Ach-induced vessel relaxation was assessed after vessels were incubated for 20 min with the NO synthase inhibitor Nω-nitro-arginine methyl ester (l-NAMN, 10^{-4} mol/L; Sigma) on the same vessel precontracted with NE (10^{-5} mol/L).

After the functional analyses, the mesenteric artery was incubated in Ca^{2+}-free PSS for 20 min. Then vascular wall thickness and lumen diameter were measured at 45 mmHg intraluminal pressure. Media cross sectional area (CSA) was calculated by subtraction of internal CSA from external CSA with the following equation: \([CSA = \pi/4(Dc^2 - Di^2)}\), where \(Dc\) and \(Di\) were external and internal lumen diameters respectively. The media-to-lumen ratio was calculated by wall thickness/ lumen diameter.

For functional studies of carotid arteries, a segment of right common carotid artery was dissected and mounted onto pressure myograph. Vessels were equilibrated in PSS at 37°C for 60 min with 80 mmHg intraluminal pressure, then the vasoconstriction and vasorelaxation responses to phenylephrine or Ach (Sigma) were performed.

**Fat incubation studies of mesenteric arteries.** Mesenteric arteries were homogenized and lysed in E-PER lysis buffer (Thermo Scientific Inc.) supplemented with protease inhibitor cocktail (Roche, Branchburg, NJ). Protein concentration was assessed using BCA Protein Assay Kit (Thermo Scientific Inc.), and equal amounts of protein were resolved by SDS-PAGE and then transferred to polyvinylidene fluoride membranes by electroblotting. Nitrotyrosine expression was detected using a mouse anti-nitrotyrosine monoclonal antibody (Abcam, Cambridge, MA).

**Statistical analysis.** All data are presented as mean ± SE. Statistical analysis was done using GraphPad Prism software (GraphPad, La Jolla, CA). Results were analyzed using the unpaired t test for comparison between two groups. For multiple comparisons, results were analyzed using one-way or two-way ANOVA, followed by Tukey or Bonferroni post-test analysis. Probability values of \(P < 0.05\) were considered statistically significant.

**RESULTS**

**Metabolic parameters.** Body weight, gonadal fat pad weight, mesenteric perivascular fat weight, and fasting blood glucose levels were elevated after 10 weeks of DIO compared with mice fed the standard diet, irrespective of genotype (\(n = 5–7\) per group; Table 1). Body weight was similar between DIO Psgl-1/+ mice and DIO Psgl-1−/− mice (\(P > 0.05\)). Plasma free-fatty acid (FFA) levels in DIO Psgl-1−/− mice were significantly elevated compared with other groups (Table 1). Fasting plasma insulin levels and systolic blood pressure (BP) levels were similar between the groups, irrespective of diet and genotype (\(n = 5–7\) per group) (Table 1). The HOMA-IR was significantly increased in DIO Psgl-1−/− mice compared with standard chow-fed Psgl-1+/+ and Psgl-1−/− mice (Table 1). To verify the reliability of BP measurement using tail cuff, a positive control was performed using NE (0.2 mg/kg) injection subcutaneously. After the NE injection, the BP increased to 159.1 ± 6.3 mmHg compared with 112.0 ± 5.1 mmHg in a 0.9% NaCl-injected group (\(n = 3\) per group, \(P < 0.01\)).

**Circulating levels of sP-sel, sE-sel, MCP-1, and leptin.** To determine the effect of DIO and Psgl-1 deficiency on a panel of circulating biomarkers, the levels of sP-sel, sE-sel, MCP-1, and leptin were measured from Psgl-1+/+, DIO Psgl-1+/+, Psgl-1−/−, and DIO Psgl-1−/− mice. The levels of sP-sel and sE-sel in mice fed standard chow were significantly reduced in Psgl-1−/− and DIO Psgl-1−/− mice compared with Psgl-1+/+ and DIO Psgl-1−/− mice (Fig. 1A). DIO did not affect the levels of MCP-1 in either group (Fig. 1A). Leptin levels were significantly increased in DIO Psgl-1−/− and DIO Psgl-1−/− mice compared with lean control groups (Fig. 1A). Other circulating inflammatory

FIG. 1. Circulating levels, expression of biomarkers, and macrophage content in control and DIO mice (n = 6–8 per group). A: Circulating levels of sP-sel, sE-sel, MCP-1, and leptin. B: Expression of IL-6, MCP-1, leptin, and Psgl-1 in mPVAT and Psgl-1 in mesenteric arteries (MA). C: Macrophage content in mPVAT. Arrows: Mac-3-positive macrophages. Scale bar: 100 um. *P < 0.01; **P < 0.05. (A high-quality color representation of this figure is available in the online issue.)
cytokines, including IL-1β, IL-6, and tumor necrosis factor-α (TNF-α), were tested but were below detection range.

Expression levels of IL-6, MCP-1, leptin, and Psgl-1.

To characterize the effect of DIO on mPVAT, the mRNA expression levels of IL-6, MCP-1, leptin, and Psgl-1 were assessed using real-time PCR. The expression levels of IL-6 and MCP-1 were significantly increased in DIO Psgl-1+/− mice compared with standard chow-fed Psgl-1+/+ mice and were significantly reduced in DIO Psgl-1−/− mice compared with DIO Psgl-1+/− mice (Fig. 1B). The leptin levels were significantly increased in DIO Psgl-1+/+ and DIO Psgl-1−/− mice compared with control groups (Fig. 1B). The levels of Psgl-1 in mPVAT and mesenteric arteries were significantly higher in DIO Psgl-1+/− mice compared with standard chow-fed Psgl-1+/+ mice (Fig. 1B).

Macrophage accumulation in perivascular adipose tissue. To determine the effect of DIO and Psgl-1 deficiency on perivascular adipose tissue inflammation, macrophages were quantitated from fat surrounding mesenteric arteries using Mac-3 immunostaining (Fig. 1C). The macrophage content of mPVAT was increased in DIO Psgl-1+/+ mice compared with standard chow-fed Psgl-1+/+ mice, but the mPVAT macrophage content was significantly reduced in DIO Psgl-1−/− mice compared with DIO Psgl-1+/+ mice (Fig. 1C).

Vascular superoxide and nitrotyrosine in mesenteric arteries. As a measure of local oxidative stress, vascular superoxide was measured from cross-sections of mesenteric arteries using DHE staining (Fig. 2). Superoxide staining was significantly increased in mesenteric arteries of DIO Psgl-1+/+ mice compared with standard chow-fed Psgl-1+/+ mice; however, superoxide staining in DIO Psgl-1−/− mice was reduced compared with DIO Psgl-1+/+ mice and was not different between standard chow-fed Psgl-1+/+ or Psgl-1−/− mice.

Protein expression levels of nitrotyrosine were determined by immunoblotting. Nitrotyrosine protein expression in mesenteric arteries was increased in DIO Psgl-1+/+ mice, but not in standard chow-fed Psgl-1+/+ mice and DIO Psgl-1−/− mice (Fig. 2F).

Morphology and vascular function of mesenteric and carotid arteries. The morphologic properties of mesenteric arteries were characterized in Ca2+-free conditions. No significant differences were detected in baseline lumen diameter, wall thickness, media-to-lumen ratio, and media cross-sectional area among the groups (Table 2). NE-induced concentration-dependent contractile responses in mesenteric arteries were similar between Psgl-1+/+ mice and Psgl-1−/− mice fed both standard chow and HFD (Fig. 3A). Endothelium-independent vasorelaxation responses to SNP were also similar between the groups (Fig. 3B). Endothelium-dependent vasorelaxation was evaluated with Ach. Vasorelaxation responses to Ach were significantly reduced in DIO Psgl-1+/+ mice compared with standard chow-fed Psgl-1+/+ mice; however, DIO Psgl-1−/− mice were protected against endothelial dysfunction with responses similar to standard chow-fed Psgl-1+/+ and Psgl-1−/− mice (Fig. 3C). Ach-induced vasorelaxation was inhibited in all groups after preincubation with L-NAME (Fig. 3D). The bioavailability of NO was determined by differences in Ach-induced maximal vasorelaxation in the presence and absence of L-NAME. NO-mediated relaxation was significantly reduced in DIO Psgl-1+/+ mice compared with standard chow-fed Psgl-1+/+ mice, whereas...

NO-mediated relaxation in DIO Psgl-1<sup>+/−</sup> mice was not significantly different than in standard chow–fed Psgl-1<sup>+/−</sup> or Psgl-1<sup>+/+</sup> mice (Fig. 3E).

To determine the role of superoxide in mediating endothelial dysfunction induced by DIO, vessels were incubated with the superoxide scavenger, TEMPO, for 30 min. Ach-induced vasorelaxation was significantly improved by TEMPO in DIO Psgl-1<sup>+/+</sup> mice compared with vessels without TEMPO treatment (Fig. 3F). Endothelium-independent vasorelaxation responses to SNP were similar between the groups after TEMPO treatment (Fig. 3G). After treatment of TEMPO, superoxide staining by DHE in vessels of DIO Psgl-1<sup>+/+</sup> mice was reduced compared with vessels without TEMPO treatment (Fig. 3H).

To assess the potential effect of systemic inflammation induced by DIO on carotid arteries, the pressure myograph was used to test vascular function on carotid arteries from standard chow-fed and DIO Psgl-1<sup>+/+</sup> mice. Phenylephrine-induced concentration-dependent contractile responses (Fig. 4A), and Ach-induced concentration-dependent relaxation responses (Fig. 4B) were similar between the groups.

**Direct local effect of mPVAT on vascular function.** To determine the local effect of mPVAT on vascular function, the mesenteric arteries from standard chow-fed Psgl-1<sup>+/+</sup> mice were incubated in mPVAT from DIO Psgl-1<sup>+/+</sup> mice or DIO Psgl-1<sup>+/−</sup> mice in vitro. After incubation in mPVAT from DIO Psgl-1<sup>+/+</sup> mice, the endothelial-dependent vasorelaxation responses to Ach were significantly impaired compared with responses after incubation in mPVAT from DIO Psgl-1<sup>+/−</sup> mice (Fig. 5B). Ach-induced vasorelaxation was inhibited in both groups after preincubation with L-NAME (Fig. 5C). Vasoconstriction responses to NE and endothelium-independent vasorelaxation responses to SNP were similar between the groups (Fig. 5A and D).

**Psgl-1 neutralization is protective against obesity-induced macrophage accumulation in perivascular adipose tissue and endothelial dysfunction.** To test the potential therapeutic strategy of Psgl-1 blockade, 5 weekly injections of a Psgl-1–blocking antibody or control isotype were given to DIO Psgl-1<sup>+/+</sup> mice. After this regimen, the macrophage content of mPVAT was significantly reduced in DIO Psgl-1<sup>+/+</sup> mice that received the antibody compared with control isotype-injected DIO Psgl-1<sup>+/+</sup> mice (Fig. 6D). This reduced perivascular adipose tissue macrophage content did not affect NE-induced vasoconstriction responses (Fig. 6A) but did improve Ach-induced vasorelaxation (Fig. 6B). The endothelial-independent responses to SNP were similar between the groups (Fig. 6C).

**DISCUSSION**

Obesity is an inflammatory disease (11) and a risk factor for cardiovascular diseases (12,13). One of the earliest detectable vascular abnormalities associated with obesity is impaired vascular relaxation (4). Impaired vascular function has been shown to be predictive of later cardiovascular complications (14). This early endothelial dysfunction is associated with circulating markers of inflammation, suggesting interplay between leukocyte activity and endothelial properties (15). Currently, weight loss and physical activity are the most effective means to prevent or reduce these vascular abnormalities (16); however, sustained weight loss is difficult to achieve, so treatments designed to prevent the vascular effects of obesity are needed.

One of the mechanisms responsible for endothelial dysfunction in obesity may be accumulation of perivascular fat (17). Epicardial fat that overlies the heart and coronary arteries, as well as perivascular fat surrounding large arteries, are associated with vascular lesions (18–20) and may be causally related to local and systemic atherosclerosis. For example, transplantation of visceral fat to carotid arteries of atherosclerotic-prone mice triggered formation of a local atherosclerotic lesion, whereas transplantation of subcutaneous fat did not (21). An interaction between the visceral or perivascular adipocyte and infiltrating macrophages may be contributing to the adverse vascular effects of excess visceral adiposity.

Adipose tissue macrophage content increases in obesity, and this corresponds to increased expression of adipose tissue-related inflammatory cytokines (11). Inflammatory adipose tissue is preceded by increased leukocyte-endothelial interactions within the visceral fat depots (3,22). Adhesion molecules, including selectins, were up-regulated in obese adipose tissue and participated in leukocyte recruitment (22). Mice deficient in Psgl-1 had reduced visceral adipose tissue macrophage content in the setting of obesity (8). Leukocyte Psgl-1 deficiency may therefore protect against the adverse vascular consequences of excess visceral adiposity.

Because endothelial dysfunction represents an early manifestation of vascular disease, we tested whether Psgl-1 deficiency would be protective against endothelial dysfunction in the setting of obesity. In this research, we studied mesenteric arteries because they are particularly amenable to analyses with arterial pressure myography. These arteries also become surrounded by visceral adipose tissue in the setting of obesity and are prone to atherosclerosis (23). This model thus allows us to study inflammatory characteristics of endogenous visceral adipose tissue and endothelial function involving adjacent arteries.

We used a 10-week DIO protocol because mice gain considerable weight and develop clear evidence of adipose tissue inflammation at this time point (8). Compared with lean mice, DIO mice in this study developed marked impairment of endothelial function. To perform this measure,
FIG. 3. Vasoconstriction and vasorelaxation responses of mesenteric arteries (MA) and DHE fluorescence of MA after treatment with TEMPOL. Control, DIO Psgl-1+/+, and Psgl-1−/− mice (n = 5–7 per group). A: Concentration response to NE. B: Concentration response to SNP. C: Concentration response to Ach. D: Concentration response to Ach after preincubation in L-NAME. E: L-NAME-sensitive maximal vasorelaxation responses to Ach. F: Concentration response to Ach of MA from DIO Psgl-1−/− after treatment with TEMPOL. G: Concentration response to SNP of MA from DIO Psgl-1−/− after treatment with TEMPOL. H: DHE fluorescence of MA from DIO Psgl-1−/− without (left) and with (right) TEMPOL treatment. Scale bar: 50 μm. *P < 0.05 compared with DIO Psgl-1−/− mice, control Psgl-1−/− mice, and control Psgl-1+/+ mice. #P < 0.05 compared with vessels without TEMPOL treatment. (A high-quality color representation of this figure is available in the online issue.)
it was necessary to clear the tissue surrounding the vessel, including the adipose tissue. Thus, the dysfunction observed does not require the immediate presence of the perivascular adipose tissue and likely reflects a chronic effect of the adipose tissue on the endothelium. Anatomic measurements of the mesenteric arteries harvested from the obese and lean mice were similar; however, more macrophages were present in the perivascular adipose tissue and adjacent arteries from the DIO mice. This was associated with increased vascular superoxide and nitrotyrosine protein expression supporting the hypothesis that local excessive oxidative stress in the vessel wall leads to reduced endothelial NO bioavailability. The current study showed that the expression levels of inflammatory biomarkers are significantly elevated in mesenteric perivascular fat from DIO Psgl-1<sup>+/+</sup> mice. The carotid arteries,
which lack robust perivascular fat pads, did not show endothelial dysfunction, suggesting that local perivascular fat from DIO mice contributes more to vascular dysfunction than systemic effects in obesity.

Because we have previously shown that Psgl-1 deficiency leads to reduced adipose tissue inflammation in the setting of obesity (8) we tested the effect of Psgl-1 deficiency on endothelial dysfunction induced by obesity. As expected, Psgl-1 deficiency in DIO mice led to reduced accumulation of macrophages within the perivascular mesenteric adipose tissue. This was associated with reduced vessel wall superoxide content and nitrotyrosine. Previous research has demonstrated that excessive reactive oxygen species (ROS) are important in vascular dysfunction in different animal models of metabolic syndrome (24–26), and ROS are produced by multiple cell types, including endothelial cells, smooth muscle cells, and infiltrating inflammatory cells in the vasculature (25). NADPH oxidases and the mitochondria respiratory chain are major source of ROS in the vasculature (26,27).

The responsible cellular and enzymatic source of vascular superoxide in our study remains to be determined. The vessel wall superoxide appeared to be causally related to the endothelial dysfunction because the obesity-induced endothelial dysfunction was improved after treatment with the superoxide scavenger, TEMPOL. However, because TEMPOL only partially recovered endothelial dysfunction induced by the HFD, other factors may contribute to reduced NO bioavailability. Future in vivo experiments with TEMPOL or other antioxidants might be useful to reveal the relative importance of this mechanism.

Importantly, Psgl-1 deficiency prevented the endothelial dysfunction induced by DIO, presumably due to reduced perivascular adipose tissue inflammation and vessel wall oxidative stress. A supernatant prepared from obese homogenized fat was sufficient to induce endothelial dysfunction, and this effect was not present when the supernatant was prepared from obese Psgl-1–deficient fat. Although this fat supernatant experiment may not be reflective of the in vivo setting, because cells are homogenized, it supports the concept that an inflammatory factor derived from fat triggers local endothelial dysfunction and that this is reduced in the setting of Psgl-1 deficiency. Previous research reported that supernatants from inflammatory fat showed strong chemoattractant effects on leukocytes in vitro (28) and that several fat-derived inflammatory cytokines, such as IL-1β, IL-6, and TNF-α, are associated with increased NADPH oxidase expression and endothelial dysfunction (27,29–31). Identification of the specific downstream factor responsible for the Psgl-1 effect in our model will require further studies.

To determine whether Psgl-1 inhibition might be effective therapy for endothelial dysfunction associated with obesity, DIO Psgl-1+/- mice were treated with weekly injections of an antibody that blocks interactions between selectins and Psgl-1. Antibody injections were initiated at week 5, in the middle of the 10-week DIO protocol, to determine if Psgl-1 could prevent endothelial dysfunction while mice were in the process of gaining weight. Psgl-1 blockade in this setting was effective in reducing adipose tissue inflammation, endothelial dysfunction, and vascular superoxide production.
In the present study, we found that the HOMA-IR index was significantly increased in DIO Psgl-1−/− mice compared with lean control mice, as expected. In DIO Psgl-1−/− mice, HOMA-IR showed a trend toward protection, although it was not significant compared with DIO Psgl-1−/+ mice. FFA levels were also significantly decreased in DIO Psgl-1−/− mice compared with DIO Psgl-1−/+ mice, suggesting that Psgl-1 deficiency may correct other metabolic abnormalities in the setting of obesity. The underlying mechanisms responsible for this effect will also require additional study.

In conclusion, Psgl-1 deficiency is protective against obesity-induced endothelial dysfunction. Therapies designed to inhibit Psgl-1 binding to selectins may be useful to reduce preclinical vascular abnormalities associated with obesity.
